

# 1. Pareto Distribution

Welcome to the series of E-learning modules on Pareto Distribution. Here, we will discuss about the distribution function, mean, variance, raw moments, skewness and kurtosis, moment generating function, median, mode, method of obtaining conditional distribution, uses, applications, and examples of the distribution.

By the end of this session, you will be able to:

- Explain the Pareto distribution
- Explain the distribution function
- Explain the mean and variance
- Explain the raw moments, skewness and kurtosis
- Explain the moment generating function
- Explain the median and mode
- Explain the uses, applications and examples

The Pareto distribution, named after the Italian economist Vilfredo Pareto, is a power law probability distribution that coincides with social, scientific, geophysical, actuarial, and many other types of observable phenomena. Outside the field of economics, it is sometimes referred to as the Bradford distribution.

The Pareto distribution is a skewed, heavy-tailed distribution that is sometimes used to model the distribution of incomes and other financial variables. As the distribution is heavy-tailed, it can have large values, which makes it a tool for analyzing extreme values.

A continuous random variable  $X$  is said to have Pareto distribution with parameters  $\alpha$  and  $b$  if its probability density function is given by,  
 $f(x)$  is equal to  $\alpha$  into  $b$  power  $\alpha$  divided by  $x$  power  $\alpha + 1$ , where  $x$  is greater than or equal to  $b$  and  $\alpha$  is greater than 0.

Here,  $\alpha$  is called shape parameter and  $b$  is called scale parameter.

Since  $f(x)$  is a probability density function, we can write

Integral from  $b$  to infinity,  $f(x) dx$  is equal to 1 implies  $\alpha$  into  $b$  power  $\alpha$  into integral from  $b$  to infinity  $x$  power minus  $\alpha$  minus 1  $dx$  is equal to 1

Implies integral from  $b$  to infinity  $dx$  is equal to 1 divided by  $\alpha$  into  $b$  power  $\alpha$

Let us define incomplete gamma integral,

Integral from  $\beta$  to infinity  $e$  power minus  $x$  into  $x$  power  $\alpha$  minus 1  $dx$

Is equal to  $\Gamma(\alpha, \beta)$ ,

Is equal to  $\alpha$  minus 1 factorial into  $e$  power minus  $\beta$  into summation over  $k$  is equal to zero to  $\alpha$  minus 1  $\beta$  power  $k$  divided by  $k$  factorial

## 2. Distribution Function, Mean and Variance

Let us obtain the distribution function of the Pareto distribution.

Distribution function is given by,

$F(x)$  is equal to integral from  $b$  to  $x$  of  $f(x) dx$

Is equal to integral from  $b$  to  $x$ ,  $\alpha$  into  $b^\alpha$  divided by  $x^{\alpha+1} dx$

Is equal to  $\alpha$  into  $b^\alpha$  into integral from  $b$  to  $x$ ,  $x^{-\alpha-1} dx$

Is equal to  $\alpha$  into  $b^\alpha$  into  $x^{-\alpha}$  divided by  $-\alpha$ , ranges from  $b$  to  $x$

Is equal to  $-b^\alpha$  into  $x^{-\alpha}$  minus  $-b^{-\alpha}$

Is equal to  $1 - b^\alpha$  divided by  $x^\alpha$ , for  $x$  greater than or equal to  $b$

Now, let us find mean of Pareto distribution.

Mean of the distribution is given by  $\mu_1$  is equal to expectation of  $X$  is equal to integral from  $b$  to infinity  $x$  into  $f(x) dx$

Is equal to  $\alpha$  into  $b^\alpha$  into integral from  $b$  to infinity  $x^{-\alpha-1} dx$

Is equal to  $\alpha$  into  $b^\alpha$  into  $1$  divided by  $\alpha - 1$  into  $b^{\alpha-1}$

Is equal to  $\alpha b$  divided by  $\alpha - 1$

Variance of the Pareto distribution is given by  $\mu_2$  is equal to  $\mu_2$  dash minus  $\mu_1$  dash whole square. Hence, first let us find  $\mu_2$  dash is equal to expectation of  $X^2$

Is equal to integral from  $b$  to infinity  $x^2$  into  $f(x) dx$

Is equal to  $\alpha$  into  $b^\alpha$  into integral from  $b$  to infinity  $x^{-\alpha-2} dx$

Is equal to  $\alpha$  into  $b^\alpha$  into  $1$  divided by  $\alpha - 2$  into  $b^{\alpha-2}$

Is equal to  $\alpha$  into  $b^2$  divided by  $\alpha - 2$

Therefore, variance

$\mu_2$  is equal to  $\mu_2$  dash minus  $\mu_1$  dash square

Is equal to  $\alpha$  into  $b^2$  divided by  $\alpha - 2$  minus  $\alpha$  into  $b$  divided by  $\alpha - 1$  the whole square

Is equal to  $\alpha$  into  $b^2$  into  $1$  divided by  $\alpha - 2$  minus  $\alpha$  divided by  $\alpha - 1$  the whole square

By taking common denominator we get,  $\alpha$  into  $b^2$  into  $\alpha - 1$  whole square minus  $\alpha$  into  $\alpha - 2$  whole divided by  $\alpha - 1$  square into  $\alpha - 2$

On simplification, we get,

$\alpha$  into  $b^2$  divided by  $\alpha - 1$  square into  $\alpha - 2$ , for  $\alpha$  greater than 2. If  $\alpha$  is 1 or 2, the variance is infinity.

# 3. Raw Moments, Skewness and Kurtosis

Now, let us obtain  $r^{\text{th}}$  raw moment of Pareto distribution.

$r^{\text{th}}$  raw moment  $\mu_r'$  of Pareto distribution is given by,

$\mu_r'$  is equal to expectation of  $x^r$

Is equal to integral from  $b$  to infinity  $x^r$  into  $f$  of  $x$   $dx$   
 Is equal to  $\alpha$  into  $b^{\alpha}$  into integral from  $b$  to infinity  $x^r$  into  $x^{\alpha-1}$   $dx$

It can be written as,  $\alpha$  into  $b^{\alpha}$  integral from  $b$  to infinity  $x^{r-\alpha}$   $dx$

Is equal to  $\alpha$  into  $b^{\alpha}$  into  $\frac{1}{r-\alpha+1}$  into  $b^{r-\alpha+1}$

On simplifying we get,  $\alpha$  into  $b^r$  divided by  $\alpha - r + 1$ .

By substituting  $r$  is equal to 1, we get,

Mean  $\mu_1'$  is equal to  $\alpha$  into  $b$  divided by  $\alpha - 1$

Substituting  $r$  is equal to 2, we get,  $\mu_2'$  is equal to  $\alpha$  into  $b^2$  divided by  $\alpha - 2$ .

Hence, variance  $\mu_2$  is equal to  $\mu_2' - (\mu_1')^2$

Is equal to  $\alpha$  into  $b^2$  divided by  $\alpha - 2$  minus  $\alpha$  into  $b$  divided by  $\alpha - 1$  the whole square

On simplification we get,

$\alpha$  into  $b^2$  divided by  $\alpha - 1$  square into  $\alpha - 2$ , for  $\alpha$  greater than 2. If  $\alpha$  is 1 or 2, the variance is infinity.

By substituting  $r$  is equal to 3, we get  $\mu_3'$  is equal  $\alpha$  into  $b^3$  divided by  $\alpha - 3$  and

$r$  is equal to 4, we get,  $\mu_4'$  is equal to  $\alpha$  into  $b^4$  divided by  $\alpha - 4$

Hence,  $\mu_3$  is equal to  $\mu_3' - 3$  into  $\mu_2'$  into  $\mu_1'$  plus  $2$  into  $\mu_1'$  cube

Is equal to  $\alpha$  into  $b^3$  divided by  $\alpha - 3$  minus  $3$  into  $\alpha$  into  $b^2$  divided by  $\alpha - 2$  into  $\alpha$  into  $b$  divided by  $\alpha - 1$  plus  $2$  into  $\alpha$  into  $b$  divided by  $\alpha - 1$  the whole cube

On simplifying the above expression, we get

$2$  into  $\alpha$  into  $\alpha + 1$  into  $b^3$  divided by  $\alpha - 1$  whole cube into  $\alpha - 2$  into  $\alpha - 3$ , for  $\alpha$  greater than 3.

$\mu_4$  is equal to  $\mu_4' - 4$  into  $\mu_3'$  into  $\mu_1'$  plus  $6$  into  $\mu_2'$  into  $\mu_1'$  square minus  $3$  into  $\mu_1'$  power 4

Is equal to  $\alpha$  into  $b^4$  divided by  $\alpha - 4$  minus  $4$  into  $\alpha$  into  $b^3$  divided by  $\alpha - 3$  into  $\alpha$  into  $b$  divided by  $\alpha - 1$  plus  $6$  into  $\alpha$  into  $b^2$  divided by  $\alpha - 2$  into  $\alpha$  into  $b$  divided by  $\alpha - 1$  the whole square minus  $3$  into  $\alpha$  into  $b$  divided by  $\alpha - 1$  whole power 4.

On simplifying the above expression, we get,  $3$  into  $\alpha$  into  $3\alpha^3$  plus  $\alpha$  plus  $3$

into  $b^4$  divided by  $\alpha - 1$  power 4 into  $\alpha - 2$  into  $\alpha - 3$  into  $\alpha - 4$ , for  $\alpha$  greater than 4.

Coefficient of skewness is given by,  $\beta_1$  is equal to  $\mu_3^2$  divided by  $\mu_2^3$   
 Is equal to  $2 \alpha \alpha + 1$  into  $b^3$  divided by  $\alpha - 1$  cube into  $\alpha - 2$  into  $\alpha - 3$  the whole square divided by  $\alpha$  into  $b^2$  divided by  $\alpha - 1$  square into  $\alpha - 2$  the whole cube

On simplifying, we get,  $4 \alpha + 1$  square into  $\alpha - 2$  divided by  $\alpha$  into  $\alpha - 3$  square.

For  $\alpha$  greater than 3, Pareto distribution is positively skewed.

Now, let us find the kurtosis of the distribution. Coefficient of kurtosis is given by,

$\beta_2$  is equal to  $\mu_4$  divided by  $\mu_2^2$

Is equal to  $3 \alpha \alpha^3 + \alpha + 3$  into  $b^4$  divided by  $\alpha - 1$  power 4 into  $\alpha - 2$  into  $\alpha - 3$  into  $\alpha - 4$  whole divided by  $\alpha$  into  $b^2$  divided by  $\alpha - 1$  square into  $\alpha - 2$  the whole square

Is equal to  $3 \alpha^3 + \alpha + 3$  into  $\alpha - 2$  divided by  $\alpha$  into  $\alpha - 3$  into  $\alpha - 4$ .

For  $\alpha$  greater than 4, the Pareto distribution has leptokurtic curve.

## 4. MGF, Median and Mode

Moment generating function of Pareto distribution is given by,

$M_X(t)$  is equal to expectation of  $e^{tX}$

Is equal to  $\int_b^{\infty} e^{tx} f(x) dx$

Is equal to  $\alpha \int_b^{\infty} e^{tx} x^{-\alpha-1} dx$

Is equal to  $\alpha \int_b^{\infty} e^{-tx} x^{-\alpha-1} dx$

Using, the incomplete gamma function, we get,

$\alpha \int_b^{\infty} e^{-tx} x^{-\alpha-1} dx = \alpha \Gamma(-\alpha, -bt)$

Is equal to  $\alpha (-bt)^{-\alpha} \Gamma(-\alpha, -bt)$

Now, let us obtain median of the distribution.

If  $M$  is the median of the Pareto distribution, then

$\int_b^M f(x) dx$  is equal to half is equal to  $\int_M^{\infty} f(x) dx$

We can consider any one of the two integrals. Let us consider the first integral and solve for  $M$

$\int_b^M f(x) dx$  is equal to half

Substituting for  $f(x)$  we get,

$\alpha \int_b^M x^{-\alpha-1} dx$  is equal to half

On integrating the function we get,

$\alpha \left[ \frac{x^{-\alpha}}{-\alpha} \right]_b^M$  is equal to half

On substituting the limits, we get,

$-\alpha \left[ \frac{M^{-\alpha}}{-\alpha} - \frac{b^{-\alpha}}{-\alpha} \right]$  is equal to half

Or  $1 - \frac{b^{-\alpha}}{M^{-\alpha}}$  is equal to half

That is  $\frac{b^{-\alpha}}{M^{-\alpha}}$  is equal to half

Implies  $M^{-\alpha}$  is equal to  $2 b^{-\alpha}$

By taking  $\alpha^{\text{th}}$  root, we get

$M$  is equal to  $b \cdot 2^{\frac{1}{\alpha}}$

Mode is that value of  $x$  for which  $f(x)$  is maximum. Observe that Pareto distribution is strictly a decreasing function. Hence, it attains its maximum at the very first value taken by the variable. That is If  $X$  has Pareto distribution with parameters  $\alpha$  and  $b$ , then  $f(x)$  attains its maximum at  $x$  is equal to  $b$ . Therefore,  $b$  is mode of the distribution.

# 5. Uses, Applications and Examples

Let us define some particular Pareto distribution.

The classical Pareto distribution has a survival function of the form

$f$  of  $x$  is equal to  $x$  divided by  $b$  whole power minus  $\alpha$ , where  $x$  is greater than or equal to  $b$ , and both  $\alpha$  and  $b$  are positive.

The probability density function of basic Pareto distribution is  $f$  of  $x$  is equal to  $\alpha$  divided by  $x$  power  $\alpha + 1$  for  $x$  greater than or equal to 1.

Feller defines a Pareto variable by transformation  $Y$  is equal to  $X$  power minus 1 minus 1 of a beta random variable of first kind with parameters  $m$  and  $n$ .

That is,  $W$  is equal to  $\alpha + b$  into  $Y$  into  $\gamma$ , has a Feller-Pareto distribution with parameters ( $\alpha$ ,  $b$ ,  $m$ ,  $n$ , and  $\gamma$ )

Let us see how to get the conditional distribution of a Pareto Variate.

The conditional probability distribution of a Pareto Distributed random variable given the event that it is greater than or equal to a particular number  $n$ , exceeding  $b$ , is a Pareto distribution with the same Pareto index  $\alpha$  but minimum  $n$  instead of  $b$ , that is in range,  $x$  is greater than or equal to  $n$  instead of  $b$ .

## Applications

Pareto originally used this distribution to describe the allocation of wealth among individuals since it seemed that a larger portion of the wealth of any society is owned by a smaller percentage of the people in that society. He also used it to describe distribution of income. This idea is sometimes expressed more simply as the Pareto principle or the "80, 20 rule", which says that 20 per cent of the population controls 80 per cent of the wealth.

However, the 80, 20 rule corresponds to a particular value of  $\alpha$ . In fact, Pareto's data on British income taxes in his *Cours d'économie politique* indicates that about 30 per cent of the population had about 70 per cent of the income.

The probability density function graph tells that the "probability" or fraction of the population that owns a small amount of wealth per person is rather high, and then decreases steadily as wealth increases. (Note that the Pareto distribution is not realistic for wealth for the lower end. In fact, net worth may even be negative.) This distribution is not limited to describing wealth or income, but to many situations in which an equilibrium is found in the distribution of the "small" to the "large".

Following are the examples which are seen as approximately Pareto-distributed:

- The sizes of human settlements (few cities, many hamlets/villages)
- File size distribution of Internet traffic which uses the TCP protocol (many smaller files, few larger ones)
- Hard disk drive error rates
- Clusters of Bose-Einstein condensate near absolute zero

- The values of oil reserves in oil fields (a few large fields, many small fields)
- The length distribution in jobs assigned supercomputers (a few large ones, many small ones)
- The standardized price returns on individual stocks
- Sizes of sand particles
- Sizes of meteorites
- Numbers of species per genus (There is subjectivity involved: The tendency to divide a genus into two or more increases with the number of species in it)
- Areas burnt in forest fires
- Severity of large casualty losses for certain lines of business such as general liability, commercial auto, and workers compensation

Consider the following illustration on Pareto distribution.

Suppose that the income of a certain population has the Pareto distribution with shape parameter 3 and scale parameter 1000. Find the proportion of the population with incomes between 2000 and 4000.

Let us solve this problem as follows.

Let  $X$  denote the income of a certain population. Hence,  $X$  has Pareto distribution with shape parameter ( $\alpha$ ) is equal to 3 and scale parameter ( $b$ ) is equal to 1000. Also find the median income.

Hence, we can write probability density function as follows:

$f$  of  $x$  is equal to  $\alpha$  into  $b$  power  $\alpha$  divided by  $x$  power  $\alpha + 1$  is equal to 3 into 1000 cube divided by  $x$  power 4, where  $x$  is greater than or equal to 1000

To find proportion of the population having income between 2000 and 4000, we need to find Probability of income between 2000 and 4000

Is equal to probability that 2000 less than  $X$  less than 4000

Is equal to integral from 2000 to 4000  $f$  of  $x$   $dx$

Is equal to 3 into 1000 cube into integral from 2000 to 4000  $x$  power minus 4  $dx$

Is equal to 3 into 1000 cube into  $x$  power minus 3 divided by minus 3, ranges from 2000 to 4000

Is equal to 1000 cube into 2000 power minus 3 minus 4000 thousand power minus 3

On simplifying the above figures, we get

Zero point 1, zero 9, 4

We know that median of the distribution is given by,

$M$  is equal to  $b$  into  $\alpha^{\text{th}}$  root of 2

Is equal to 1000 into cube root of 2 is equal to 125

Here's a summary of our learning in this session, where we understood:

- The Pareto distribution – definition through pdf
- The distribution function
- The mean and variance
- The raw moments, skewness and kurtosis
- The moment generating function
- The median and mode
- The uses, applications and examples.
